Small Molecule Identification in Untargeted Metabolomics

- Liquid chromatography (LC) coupled with tandem mass spectrometry (MS^2) widely utilized in untargeted metabolomics studies
- Challenge: Annotation of LC-MS peaks with potential molecular structures
- Most automated machine learning based approaches utilize MS information only **[CITATION]**
- LC retention time (RT) is valueable additional information for the annotation **[CITATION]**, e.g.

Retention Time (RT) Utilization

- Multiple approaches to utilize RT for molecule annotation exist
- (utilization of RT information, scalable, cross laboratories (LC-systems), RT reference free)

1) Compare measured RTs with in-house reference RTs ✓, ✗, ✗, ✗
2) Compare measured RTs with projected reference RTs ✓, ✗, ●, ✗
3) Compare measured RTs with predicted RTs ✓, ✓, ●, ●
4) Compare measured RTs with predicted RTs proxies, e.g. LogP ✓, ✓, ✓, ✗
5) Compare measured retention orders with predicted ones ●, ✓, ✓, ✓

- Fully supported: ✓, Partially supported: ●, Not supported: ✗
- RT comparison to prune candidate lists or (re)ranking **[CITATION]**

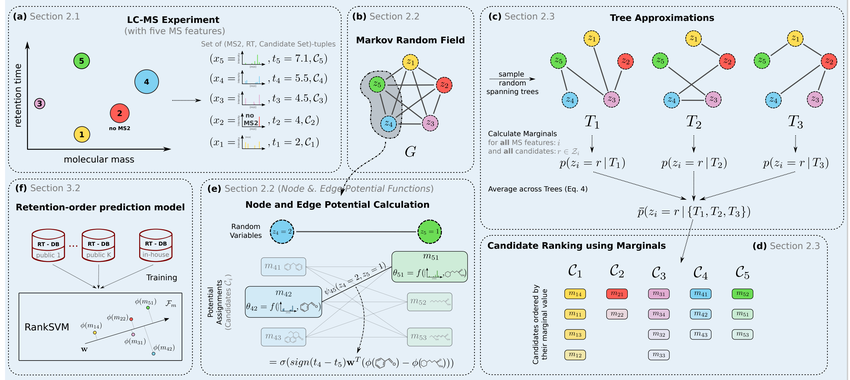
LC-MS Experiment Data and its Formal Representation

- Assume data arises from LC-MS experiment (after peak-picking and alignment)
- Available information: MS^1, RT and (etwaige only for some peaks) MS^2
- Molecular candidate lists are assumed to be given as well
- MS^2scores, e.g. MetFrag **[CITATION]**or CSI:FingerID **[CITATION]**, computed
- Data from LC-MS considered as set of N MS features:

$$\mathcal{D} = \{(x_i, t_i, \mathcal{C}_i)\}_{i=1}^{N}$$

- x_i: MS^2 spectrum (or MS^1, if no fragmentation available)
- t_i: Measured RT
- $\mathcal{C}_i$: Potentail molecular annotations for feature i, e.g. exact mass search

4. Overall Workflow



Probabilistic Framework to integrate MS and Retention Orders

- Definition of a probabilsitic graphical model superimposed on the LC-MS data
- Let $G = (E, V)$ be a complete graph
- Nodes $i \in V$ represent the MS features, Edes $(i, j) \in E$ the feature pairs
- Association of each node with discrete random variable $z_i \in \mathcal{Z}_i = \{1, \ldots, n_i\}$ ($n_i = |\mathcal{C}_i|$ number of candidates)
- Molecule annotation for complete data $\mathbf{z} = \{z_i \,|\, i \in V\} \in \mathcal{Z}_1 \times \ldots \times \mathcal{Z}_N = \mathbf{Z}$
- Intuitively: Random variable denotes which candidate is assigned to each feature.
- Pairwise Markov Random Field as probabilsitic model **?**:

$$p(\mathbf{z}) = \frac{1}{Z} \prod_{i \in V} \psi_i(z_i) \prod_{(i,j) \in E} \psi_{ij}(z_i, z_j)$$

- Ranking molecular candidates via max-marginals:

$$p_{\max}(z_i = r) = \max_{\{\mathbf{z}' \in \mathbf{Z} \,|\, z'_i = r\}} p(z_i)$$

- Intuitively, maxmimum probabilsity a candidate assignment with $z_i = r$ can achive
- Rank all candidates $r \in \{1, \ldots, n_i\}$ according to there max-marginals

Node and Edge Potentials

- Node potential function $\psi_i : \mathcal{Z}_i \to \mathbb{R}_{>0}$: goodness of the match between measured spectrum x_i and candidates of feature i
- Edge potential function $\psi_{ij} : \mathcal{Z}_i \times \mathcal{Z}_j \to \mathbb{R}_{>0}$: consistency between the observed retention order of feature i and j with the predicted retention order of the candidates z_i and z_j

Spanning Tree Approximation
